Introduction. The Strut-and-Tie is a unified approach that considers all load effects (M, N, V, T) simultaneously. The Strut-and-Tie model approach evolves as one of the most useful design methods for shear critical structures and for other disturbed regions in concrete structures. The model provides a rational approach by representing a complex structural member with an appropriate simplified truss models. There is no single, unique STM for most design situations encountered.

A strut-and-tie model (STM) idealizes the complex flow of stresses in a structural member as axial elements in a truss member. Concrete struts resist the compressive stress fields, and reinforcing steel ties resist the tensile stress fields. Struts and ties intersect at regions called nodes.

Abstract. Strut-and-tie models (STMs) are often used for the design of shear critical deep members because they can rationalize the shear transfer within discontinuous or disturbed regions in reinforced concrete structural elements. Most current codes of practice adopt the strut-and-tie method but provide very little guidance on how to select appropriate strut-and-tie layout and dimensions.

Description This course presents the concepts and application of strut-and-tie modeling (STM) for structural concrete elements. Students will identify regions within structures where STM can be used for design, apply the methodology to locate and detail reinforcement, and check the capacity of their model.
