Turboshaft Engine

A turboshaft engine is a form of gas turbine that is optimized to produce shaftpower rather than jet thrust. In concept, turboshaft engines are very similar to turbojets, with additional turbine expansion to extract heat energy from the exhaust and convert it into output shaft power. They are even more similar to turboprops, with only minor differences, and a single engine is often sold in both forms. Turboshaft engines are commonly used in applications that require a sustained high power output

Turboshafts are essentially a turbojet engine with a large shaft connect to the back of it. And since most of these engines are used on helicopters, that shaft is connected to the rotor blade transmission. Step 1: The engine operates like a turbojet, for the most part. Step 2: The power shaft attached to the turbine powers the transmission.

How The 4 Types Of Turbine Engines Work | Boldmethod

A free-turbine turboshaft is a form of turboshaft or turboprop gas turbine engine where the power is extracted from the exhaust stream of a gas turbine by an independent turbine, downstream of the gas turbine and is not connected to the gas turbine (the exhaust airflow is what spins the turbine that is connected to the shaft hence the term "free"). This is opposed to the power being extracted from the power spool via a gear box.
